

purpose of paper review. More computer coding effort is needed to convert it into a web based model for public use. The proposed model must be expanded to multiple runway orientation optimizations for modern airports. With more detailed and categorized wind data, the model also can solve the VMC, IMC or all weather wind analysis problems separately. A combined airport cost minimization model, which combines airfield land use, multiple runway orientation optimization, GIS obstruction model, and cost estimation modules, will be a long-term goal. Unfortunately, the current development of GIS does not support dynamic volumetric solving of earthwork. A GIS obstruction model has been submitted to the journal and is currently under review. The proposed optimization model for runway orientations is the essential module of the future combined model. It has been proposed earlier as a useful tool for airport design, transportation infrastructure planning, and airfield safety management.
